

## 2］Design concept

［1］Number：It might be better to be one set if possible，because it is rather difficult to obtain proper installation area and feed distribution may be unequal for plural units．We consulted with SANKI Engineering Co．Ltd which was in close association with Dorr at that time and received good answer that thickener larger than the biggest $333 \mathrm{ft} \fallingdotseq 100 \mathrm{~m} \phi$ could be available．
［2］Structure：The tailing thickener should be center post type with double slope rake arms having light structure and less required power．Bottom of the thickener should be made by tamped clay which had experienced in coal mines already at that time．So concrete should be not applied except near center post and around wall．

## 13－1－2．Calculation of required dimensions

## 1］Required water area A ：

The required area A is given by the following equation．

$$
A=\frac{Q}{v \alpha}
$$

where $Q$ ：Flow rate of up flow in the thickener
［mh h$]$
V：settling velocity
［m／h］

## $\alpha$ ：Factor

The settling velocity V was determined as $0.25 \mathrm{~m} / \mathrm{h}$ in the laboratory tests，since $V$ ，however，may be variable by reasons of variations in ore characteristics，pulp densities，temperatures etc．，the factor should be 0.6 for safety against serpentinized ore．

Then $\quad A=Q / v=1,304.75 m^{3} / h \div(0.25 m / h \times 0.6)=8,698.33 m^{2}$
So，thickener diameter can be given

$$
\begin{aligned}
& D=\sqrt{\frac{4 \mathrm{~A}}{\pi}} \\
& \text { Hence } \quad D \\
&=\sqrt{\frac{4 \times 8,698.33}{3.14}}=105.26 \mathrm{~m} \phi \rightarrow 106.0 \mathrm{~m}
\end{aligned}
$$

On thickener depth，slope of rake arms，rake revolutionary speed and installed motor power，we accepted values recommended by the manufacturer．

## 13－2．Tailing transportation piping

## 13－2－1．Calculation of required pipe diameter

Since design and construction were exerted by mechanical division of construction department，only calculations for confirmation will be described here．

1］Averaging velocity

$$
V=Q / \pi r^{2}
$$

where $\quad Q$ ：pulp flow rate $1,166.51 \mathrm{~m}^{3} / \mathrm{h} \div 3,600 \mathrm{sec} / \mathrm{h}=0.324 \mathrm{~m}^{3} / \mathrm{sec}$
$r$ ：Pipe inner radius $0.478 / 2=0.239 \mathrm{~m}$
$\pi$ ：the circular constant
Then $\quad v=0.324 \mathrm{~m}^{3} / \mathrm{sec} \div\left(3.14 \times 0.239^{2}\right)=1.806 \mathrm{~m} / \mathrm{sec}$
This value is bigger than critical flow velocity $0.83 \mathrm{~m} / \mathrm{sec}$ ，so there will be no clogging problem due to particle sedimentation．Besides that，this value is smaller than $3.0 \mathrm{~m} / \mathrm{sec}$ practically，which is boundary velocity of severe wearing so that this velocity is appropriate．

```
2] Friction loss
    Calculation of friction loss after Darcy's formula
        hs =f: L.V 
    Where hs : friction head loss [m]
    L : pipe length [m]
    D : inside pipe diameter [m]
    V : averaging velocity [m/sec]
    g : gravitational acceleration [m/\mp@subsup{sec}{}{2}]
```

## f ：friction loss coefficient

Then

$$
\text { hs }=0.02 \times \frac{100 \times 1.806^{2}}{0.478 \times 2 \times 9.8}=0.69 \mathrm{~m}
$$

Since slope of steel piping is $5 / 100$ ，head difference between 100 m equals $5 \mathrm{~m}>0.69 \mathrm{~m}$.
So clogging due to head loss will be not realized．Hence tailing slurry should be transported by natural gravity flow．

## 13－2－2．Piping for sharp slope

Since 910 m of level difference between mine site and tailing dam can not be covered by pipe slope of $5 / 100$ ，a few types of method trough，fish ladder etc． have been discussed except drop tank systems which were successfully experienced at the initial period of designing．From view point of costs，trough system was adopted consequently．The troughs were designed with slope of $1 / 6$ ．The tailing slurry，however， flowed with much higher speed than that of plan，so that many problems such as spill out of trough，slurry leakage from breathing pipes and extraordinary quick wearing of trough liners had issued．So the system was changed to the drop tank system finally． The liner material was anti－corrosion and anti abrasive special steel developed by Nippon Steel Corporation for dredge of mar ine bottom．So we expected excellent performance of newly developed material．But wearing progressed with speed higher than ten times of planed life and no anti－wearing effect was found．

## 13－3．Banking facilities

13－3－1．Basic banking
1］Design concept
Since it is difficult to dispose cyclone over flow by cyclone under flow sand only at the start－up stage of operation，basic banking with $1,500 \mathrm{~m}$ length should be constructed by soil and gravel dug by bull dozers in the dam site area．

Clay core should be inserted in the center of the banking to enhance water tightness．

## 2］Tailing disposal area

By original proposed disposal area of $3,700,000 \mathrm{~m}^{2}$ ，the total tailing tonnage of whole life of the mine will be disposed．

Soil volume for banking：$\quad 850,000 \mathrm{~m}^{3}$
Area for sand pile：$\quad 1,700,000 \mathrm{~m}^{2}$
Area for slime pond ：2，000，000 m²
Spill way（culvert）should be constructed on dam bottom to discharge top clear layer of the slime and flow in rain water．

## 13－3－2．Banking cyclones

1］Cyclone selection

After graph of Krebs Engineers，the capacity of D15B at pressure drop of 14 psi is 500 GPM $=1,900 \mathrm{\ell} / \mathrm{min}$ ．

Based on this capacity and material balance described in section 13－1－1． Design concept，1］required number of the cyclone N will be

$$
N=1,166.51 \mathrm{~m}^{3} / \mathrm{h} /\left(1.90 \mathrm{~m}^{3} / \mathrm{min} \times 60 \mathrm{~min} / \mathrm{h}\right)=10.2 \rightarrow 10 \text { sets. }
$$

Surplus units of the cyclone will be not necessary，because spigot density of the tailing thickener will be probably higher．Besides that，two lines of the cyclones will be installed actually running only one line，several sets will serve as stand－by．

14．Water facilities
14－1．Water program
1］Water balance

Flow－in ：575． $00+575.00+65.22=1,215.22 \mathrm{~m}^{3} / \mathrm{h}$
Flow－out ：186． $11+15.57+898.54+115.00=1,215.22 \mathrm{~m}^{3} / \mathrm{h} \cdots 0 \mathrm{~K}$

## 2］Design concept

Fresh water will be pumped up from both the Mamut River and the Bambangan River and cover whole demand of the mine except drinking water．Because of topography of rugged mountains in near district of the mine，there is no big river and seasonal fluctuation of flow rate between dry and rainy season and hourly change between fine and rainy weather are both extremely big．Survey of water flow rate，location of pump stations，planning of water taking－inwill be very important to maintain stable water supply．Lack of the fresh water should be appropriated by recycled water as thickener over flow．
The ratio of fresh water to recycled water is $53 \%$ to $47 \%$ ，respectively．
As the flow－out points， $10 \%$ of the fresh water should be estimated at miscellaneous losses including evaporation．A part of the fresh will be used for other office and plants except the mill，also for cooling，washing，solvent for slime milk at the mill． The rest will over flow into the recycle water tank．Hourly fluctuation of water demand will be big and especially the demand of other sections beside the mill will be expected to drop extremely at night．Plural number of water pumps should be installed at each pump station to cope with hourly demand fluctuation．

## 14－2．Selection of water pumps

1］Diameters of pipings
The flow rates of standard water pumps are designed at the rate of 2～ $3 \mathrm{~m}^{3}$／second on both of suction and delivery sides．Generally speaking，diameters are same on both sides or suction side is bigger．The standard flow rates are shown in the following table．

Relationships between pump diameters and standard flow rates

| Diameters（mm） | 38 | 50 | 65 | 75 | 100 | 125 | 150 | 175 | 200 |
| :--- | :--- | :--- | :---: | :---: | :---: | :---: | :---: | :--- | :--- |
| Flow rates $\left(\mathrm{m}^{3} / \mathrm{min}\right)$ | 0.13 | 0.23 | 0.42 | 0.56 | 1.1 | 1.7 | 2.5 | 3.6 | 4.8 |
| Diameters $(\mathrm{mm})$ | 250 | 300 | 400 | 500 | 600 | 700 | 800 | 900 | 1,000 |
| Flow rates $\left(\mathrm{m}^{3} / \mathrm{min}\right)$ | 7.5 | 11.0 | 21 | 33 | 47 | 65 | 84 | 105 | 130 |

Based on the above table，300A of diameter of the Mamut and Bambangan pumps may be appropriate for the flow rate of $575.00 \mathrm{~m}^{3} / \mathrm{h}=9.58 \mathrm{~m}^{3} / \mathrm{min}$ ． 350 A ，however，should be adopted to decrease friction loss for long distance．The piping diameter of the recycled water should be 400A because of the flow rate of $1,020 \mathrm{~m}^{3} / \mathrm{h}=17.0 \mathrm{~m}^{3} / \mathrm{min}$ ．

2］Calculations for pump type selection
Because of large capacities and higher heads，we should select turbine type．
Calculations on the Bambangan river pumps is shown here．
［1］Friction head loss by straight piping
Darcy＇s equation

$$
H_{s}=f \cdot \frac{L \cdot \frac{V^{2}}{D}}{2 g}
$$

［m］
$\begin{array}{llll}\text { where } & \text { L：length of strait piping } & 6,000 & {[\mathrm{~m}]} \\ & \text { D：inner diameter of straight piping } & 0.35 & {[\mathrm{~m}]} \\ \text { V：Averaging flow velocity } & 1.66 & {\left[\mathrm{~m} / \mathrm{sec}^{2}\right]} \\ \text { G：gravitational acceleration } & 9.8 & {\left[\mathrm{~m} / \mathrm{sec}^{2}\right]} \\ \text { f：friction loss coefficient } & & \\ \text { f }=0.02+1 / 2000 \mathrm{D}=0.0214 & & \\ & \mathrm{H} . & =0.0214 \times 6000 / 0.35 \times 1.66^{2} /(2 \times 9.8)=51.6 \mathrm{~m} & \end{array}$
［2］Friction head loss by bending piping，valve，\＆suction mouth
A］Bending piping
$H_{B}=\zeta_{B} \cdot \frac{V^{2}}{2 g}$
where $\quad \zeta_{B}$ ：Total friction loss coefficient by bending
$90^{\circ}$ bend $\zeta_{\mathrm{B}}=0.2 \sim 0.3,45^{\circ}$ bend $0.7 \zeta_{\mathrm{B}}$ ，
$30^{\circ}$ bend $0.7 \xi_{B}$ ， $15^{\circ}$ bend $0.42 \zeta_{B}$

Then assumed averaging $\zeta_{\mathrm{B}}$ as 0.25 and number of bends as 20 ， $H_{B}=0.25 \times 20 \times 1.66^{2} /(2 \times 9.8)=0.70 \mathrm{~m}$

B］Valves
Check valv $\quad H_{\text {ch }}=\zeta_{\text {ch }} \cdot \frac{V^{2}}{2 g}$
where $\quad \zeta_{\text {ch }}$ ：friction loss coefficient $0.8 \sim 1.2 \rightarrow 1.0$
then $\quad H_{B}=1.0 \times 1 \times 1.66^{2} /(2 \times 9.8)=0.14 \mathrm{~m}$
On sluce valve，the friction loss can be neglected in the case of larger than 300A．

C］Divergent－nozzle

$$
H_{D}=\zeta_{0} \cdot \frac{v_{1}^{2}-v_{2}^{2}}{2 g}
$$

where $\xi_{0}$ ：friction loss coefficient 0.15
$V_{1}$ ：inlet friction loss coefficient 250A 1.63 ［m／sec］
$V_{2}$ ：outlet friction loss coefficient 350A $0.83 \quad[\mathrm{~m} / \mathrm{sec}]$
Then $\quad H_{D}=0.15 \times\left(1.63^{2}-0.83^{2}\right) /(2 \times 9.8)=0.015 \mathrm{~m}$

D］Total friction head loss Ht

$$
\begin{aligned}
\mathrm{H}_{\mathrm{t}} & =\mathrm{H}_{\mathrm{s}}+\mathrm{H}_{\mathrm{B}}+\mathrm{H}_{\mathrm{ch}}+\mathrm{H}_{\mathrm{D}} \\
& =51.6+0.70+0.14+0.015=52.455 \mathrm{~m}
\end{aligned}
$$

［3］Total head H ：

$$
\mathrm{H}=\mathrm{H}_{\mathrm{A}}+\mathrm{H}_{\mathrm{t}}=(1,640-1,400)+52.455 \mathrm{~m}=292.455 \mathrm{~m}
$$

3］Calculation of required shaft power Kw

$$
\mathrm{Kw}=\frac{\mathrm{Q} \cdot \mathrm{H} \cdot \gamma}{6,114 \eta}
$$

where

$$
\begin{array}{ccl}
\text { Q: pumping capacity } & 9.58 & {\left[\mathrm{~m}^{3} / \mathrm{min}\right]} \\
\mathrm{H}: \text { total head } & 292.455 & {[\mathrm{~m}]} \\
r: \text { liquid density water } \rightarrow & 1,000 & {\left[\mathrm{~kg} / \mathrm{m}^{3}\right]} \\
\eta: \text { pump efficiency } & 74 & {[\%]}
\end{array}
$$

Relationship between pump diameter and efficiency is shown in the following table．

Pump diameter and standard efficiency

| D mm | 50 | 75 | 100 | 150 | 200 | 250 | 300 | 400 | 600 | 1,000 | 1,500 |
| :---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | :---: |
| $\eta$ | $\%$ | 45 | 55 | 60 | 70 | 73 | 74 | 75 | 76 | 78 | 80 |

Total required power： $\mathrm{Kw}=9.58 \times 292.455 \times 1,000 /(6,114 \times 0.74)=619 \mathrm{kw}$
Installed power： $619 \mathrm{kw} \times 2.5 / 3=515.8 \rightarrow 520 \mathrm{kw}$
Motors of pumps to be installed should be enforced to 2.5 times stronger in order to be able to pump up introduced water from the Mesilau River in the case of water shortage at the Mamut River．So pump specifications should be $250 \mathrm{~A} \times 6 \mathrm{~m}^{3} / \mathrm{min} \times$ $30.8 \mathrm{~kg} / \mathrm{cm}^{2} \times 520 \mathrm{kw} \times 3$ sets， 2 sets operating and 1 set stand－by．Besides that，since outlet of the delivery pipe will locate at $1,355 \mathrm{~m}$ level，after pumped water would cross over the utmost point，it is expected that situation will change to almost no load．

## 4］Mamut river pumps

Omitting calculations，only specifications are shown here．
Pumps： $250 \mathrm{~A} \times 7 \mathrm{~m}^{3} / \mathrm{min} \times 15.5 \mathrm{~kg} / \mathrm{cm}^{2} \times 300 \mathrm{kw} \times 2$ sets
Piping：$\quad 350 \mathrm{~A} \times 1,500 \mathrm{~m}$

## 5］Recycled water pumps

Omitting calculations，only specifications are shown here，too．
Pumps： $300 \mathrm{~A} \times 8.5 \mathrm{~m}^{3} / \mathrm{min} \times 7.5 \mathrm{~kg} / \mathrm{cm}^{2} \times 180 \mathrm{kw} \times 3$ sets
Piping：$\quad 400 \mathrm{~A} \times 800 \mathrm{~m}$
